# 1 Introduction

Using an anonymous and unlinkable ring signature-based forum, the way of choosing the  $K$  set of the signature ring can affect the privacy of users. In this report is demonstrated that preferential attachment makes users more anonymous and invulnerable from knowing its messages.

The simulation forum program was made in `python3` and its execution was made using 200 people and Zipf distribution to determine the number of messages of each member. Also, was parameterized the maximum number of messages from an author, in order to know which member can have worst privacy. In all cases of  $s$  from 1.3 to 2.0, the number of messages determined from the distribution is 305.
